

# Addressing Neurocognitive Late Effects in Brain Tumour Survivors

Julie Bennett MD, FRCPC

A light gray brushstroke background with irregular, feathered edges, centered on a white page. The text "No Disclosures" is written in a bold, black, sans-serif font across the middle of the brushstroke.

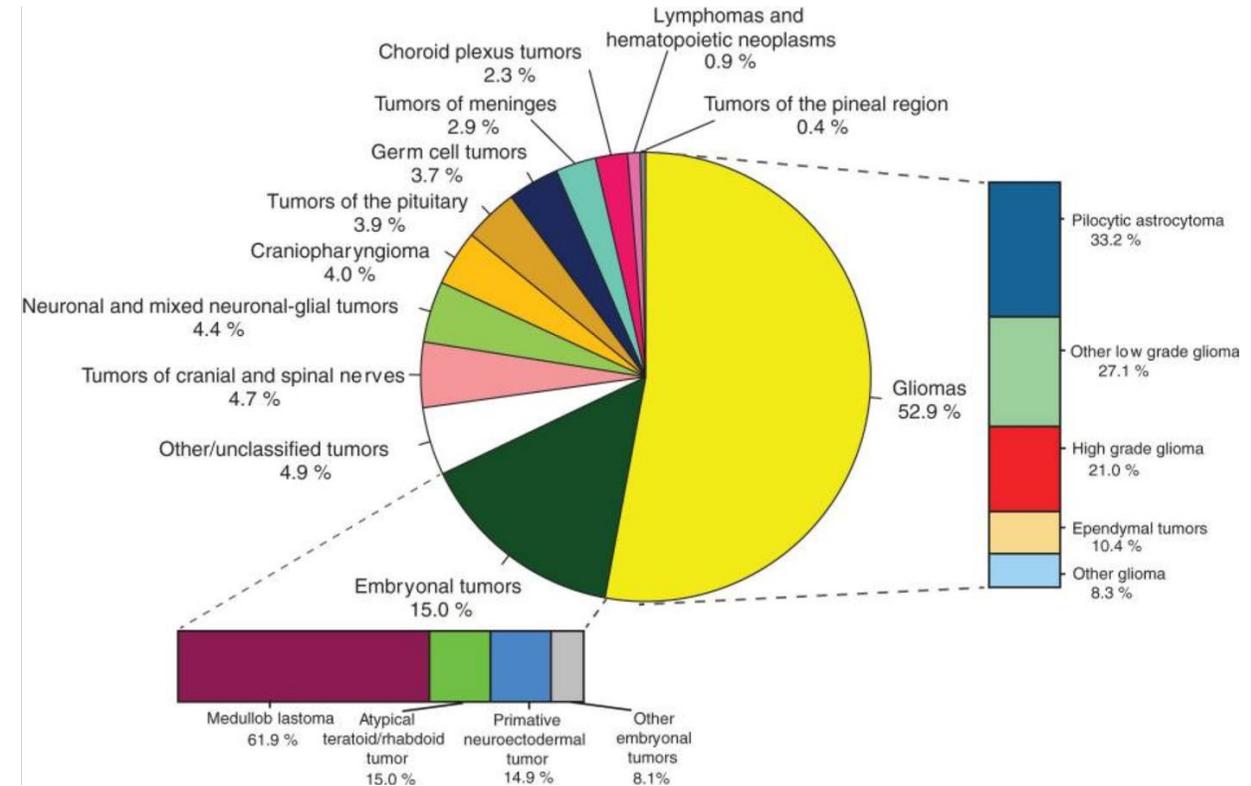

**No Disclosures**

# Objectives

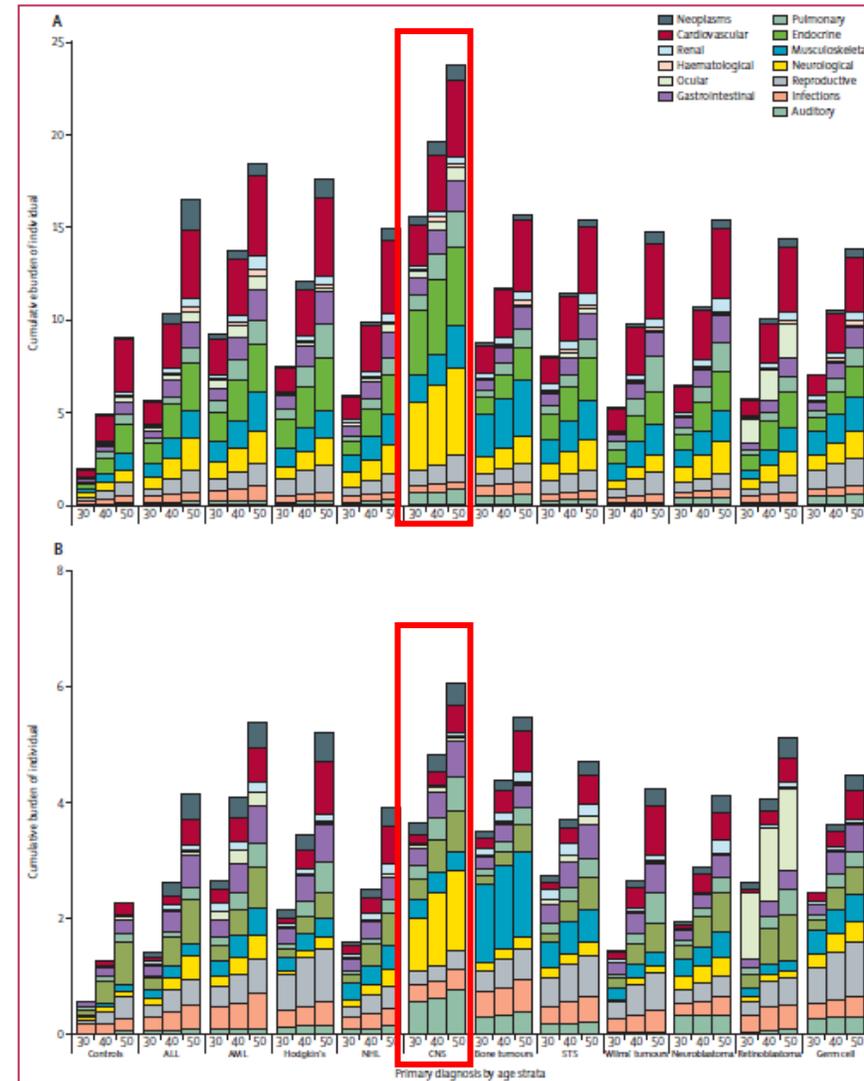

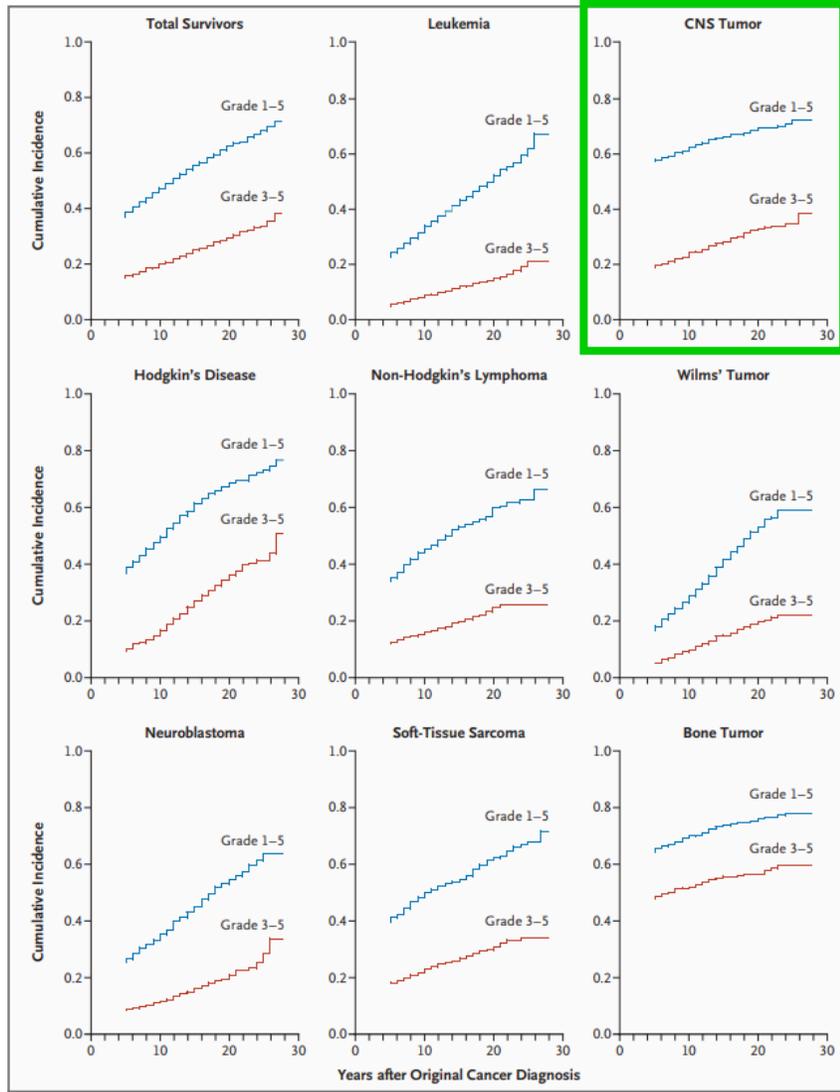

1. Understand risk factors for neurocognitive late effects in children with CNS tumors
2. Review changes in treatment paradigms to reduce neurocognitive late effects
3. Discuss strategies to improve neurocognition following treatment for CNS tumors

# Background

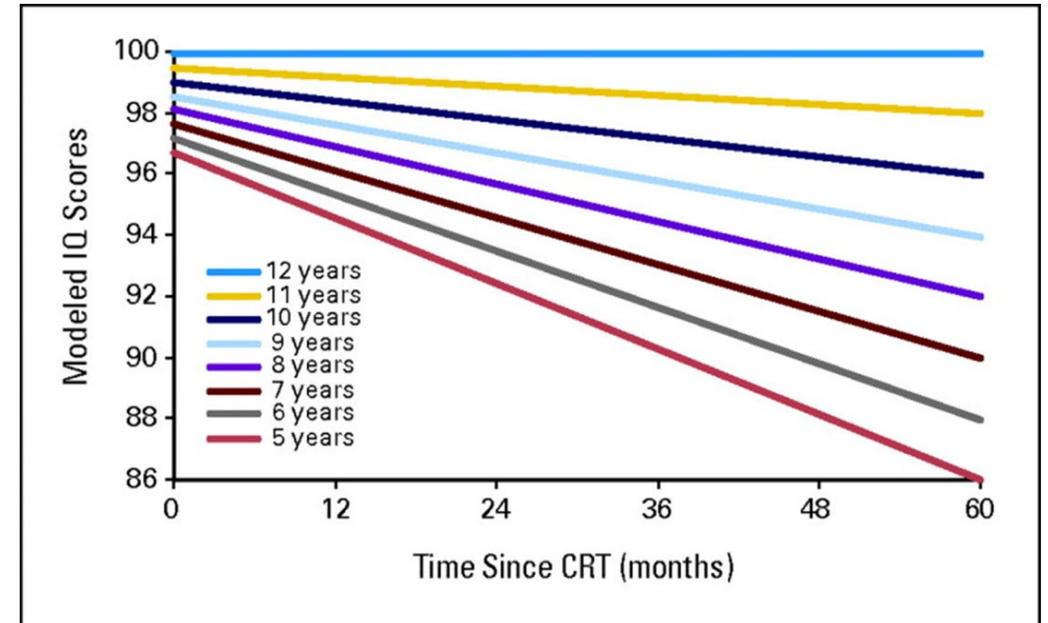

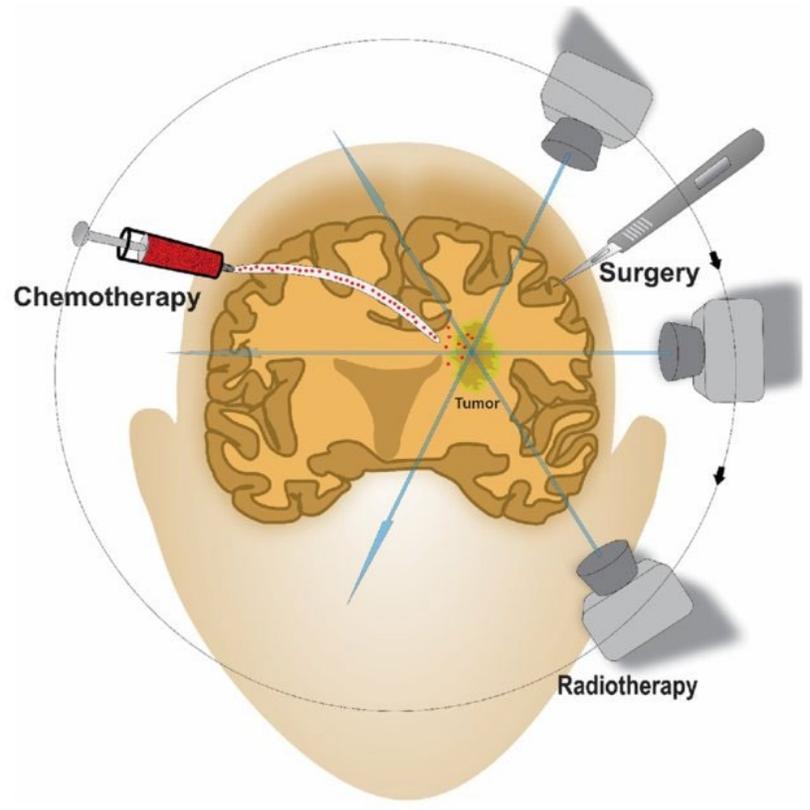

- Central nervous system (CNS) tumors are the 2<sup>nd</sup> most common cancer in children
- Most common cause of cancer-related death in pediatrics.
- 10-year survival rates ~70%

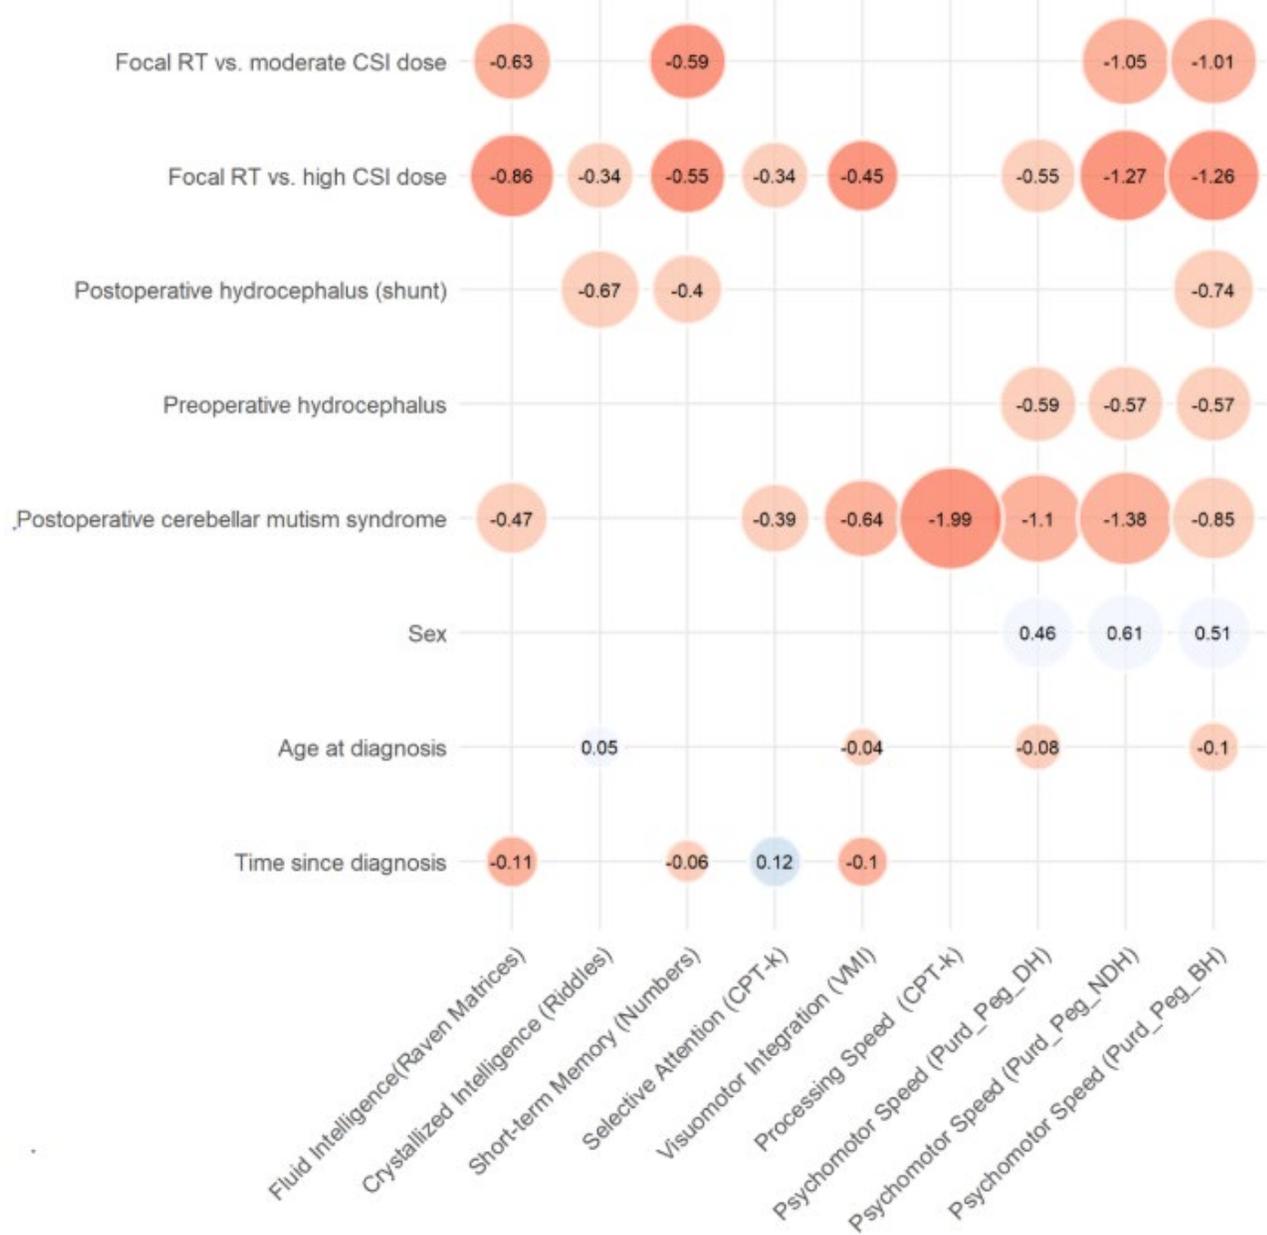

# There is significant morbidity for survivors of CNS tumors

# Multimodal treatment required with risk for neurocognitive deficits

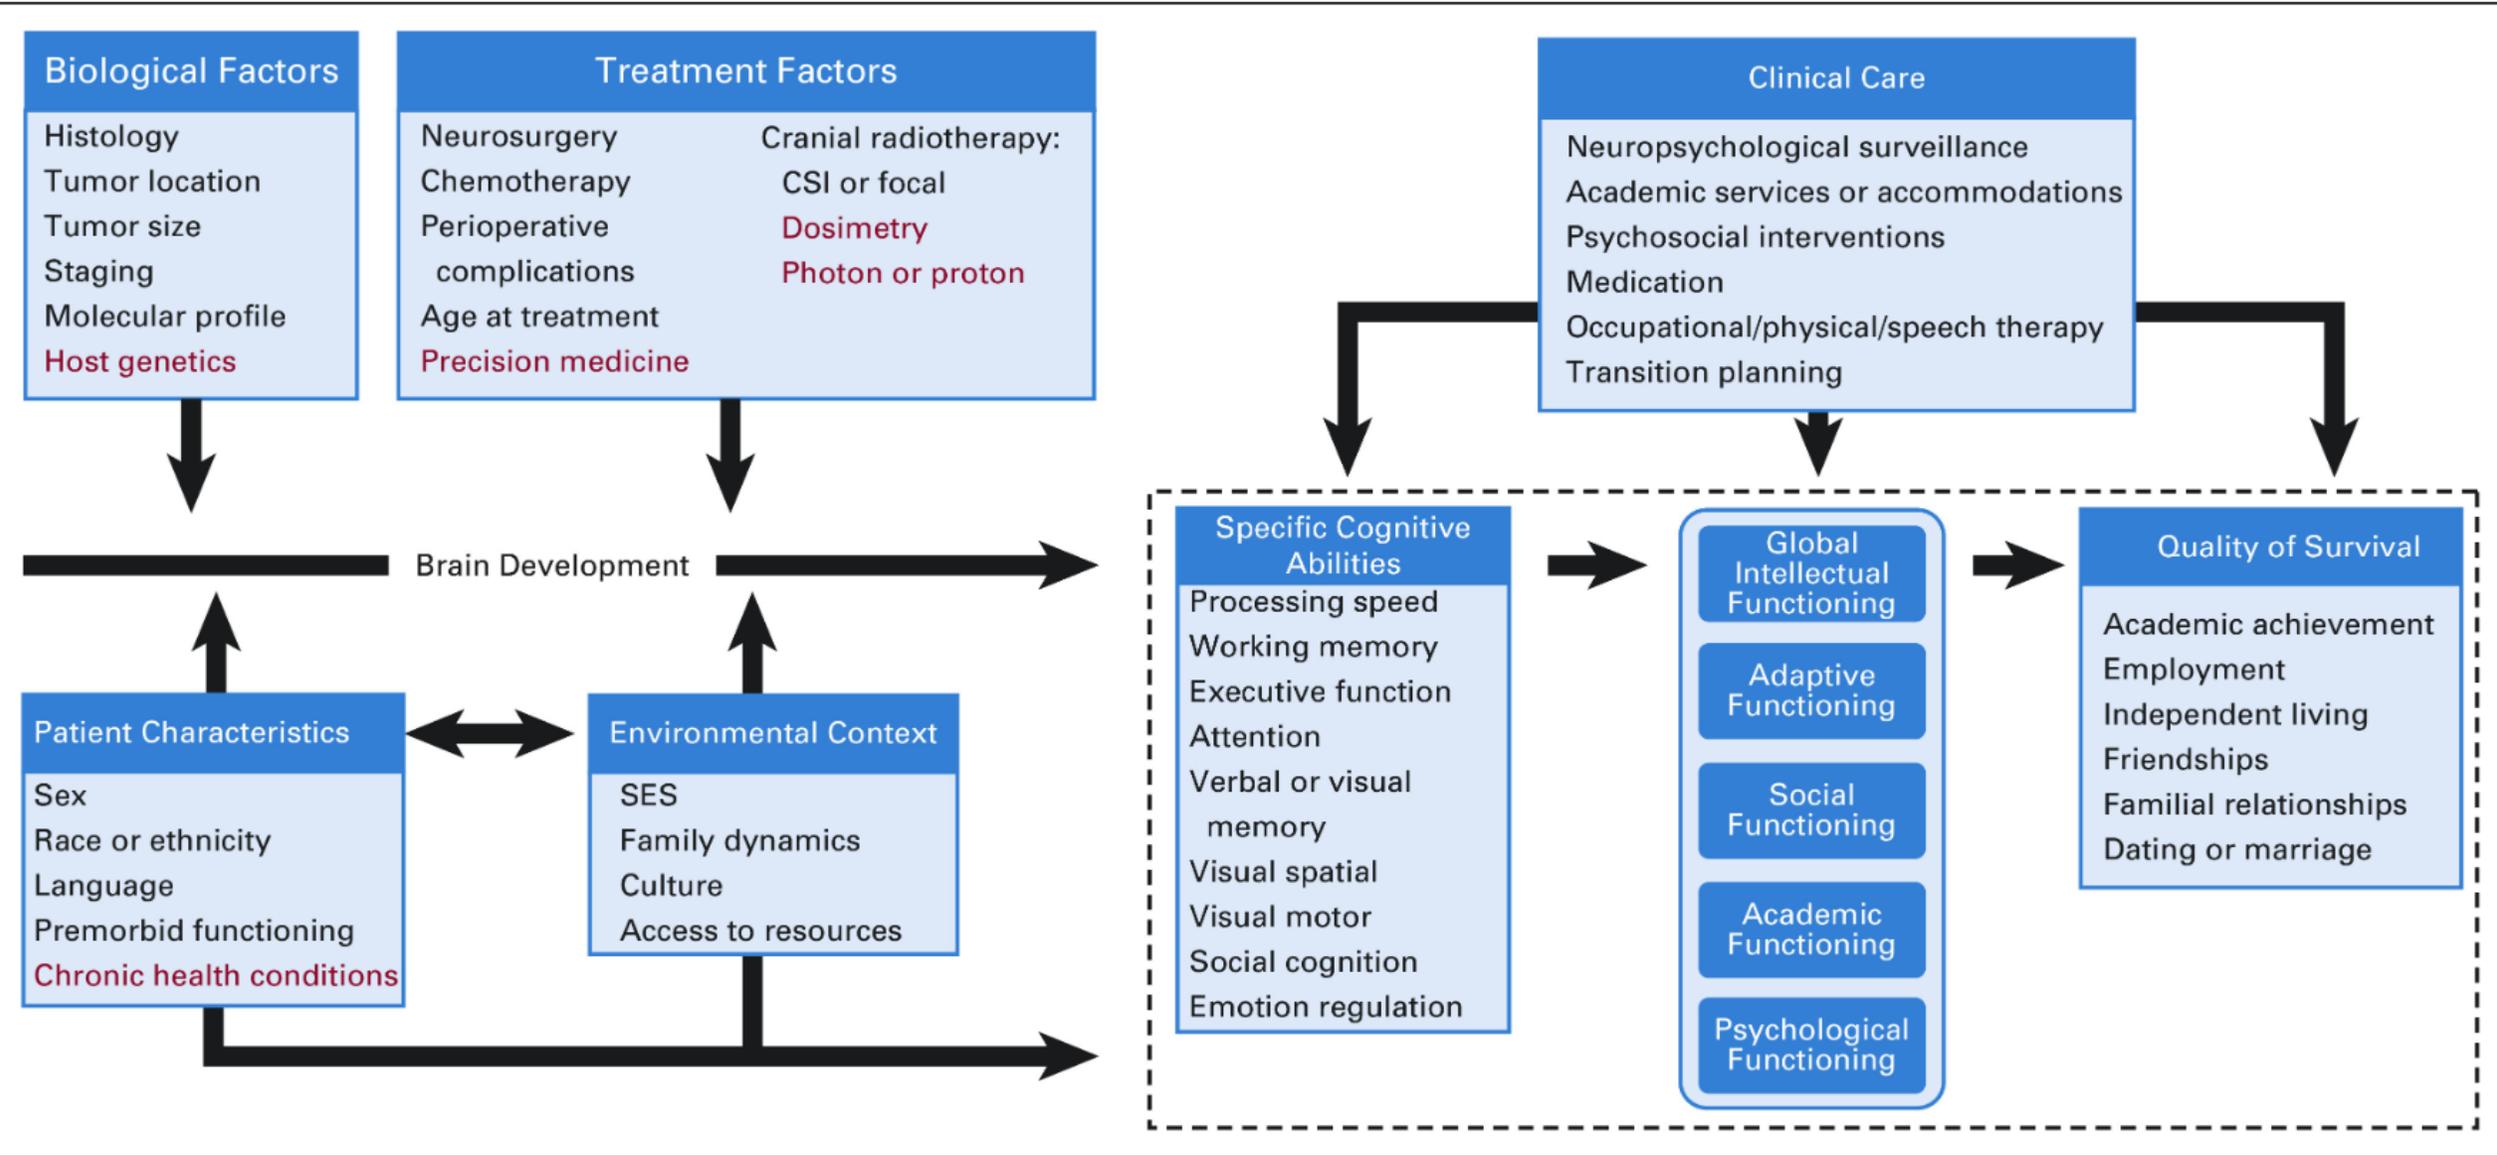

Modelled intelligence quotient (IQ) scores after CNS therapy by age ([www.cancer.gov](http://www.cancer.gov))

interpretation of effect

- negative, strong
- negative, weak
- positive, medium
- negative, medium
- positive, weak

# Complex risk factors for neurocognitive deficits

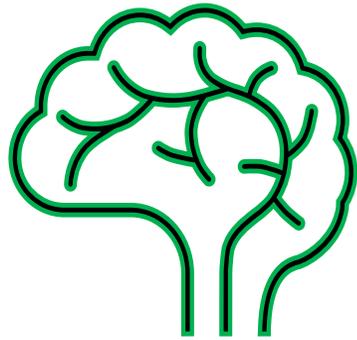

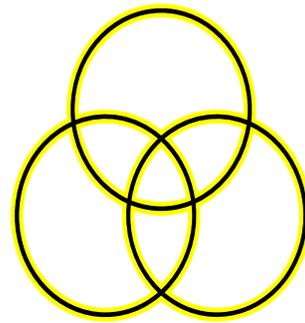

# Treatment Risk Factors

# Starting with... Medulloblastoma

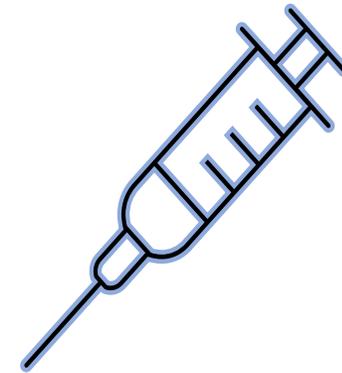

## Treatment Paradigm:

Surgery

Radiation  
(Brain and  
Spine)

Chemotherapy

# Molecular Subgroups of Medulloblastoma

## CONSENSUS

# Progress Against Medulloblastoma

...a timeline through the decades

Content researched by and supplied to *Brain Tumour* magazine by Dr Vijay Ramaswamy and Dr Eric Bouffet, The Hospital for Sick Children (SickKids), Toronto, Canada; original timeline design by Edwina Kelly (edwina@edwinakellydesign.co.uk)

EACH year medulloblastoma affects five children in every one million.

This timeline illustrates the most important breakthroughs and advances in the knowledge and management of medulloblastoma, one of the most common malignant brain tumours in children.

With recent advances in molecular and genomic technologies, the landscape of medulloblastoma is changing. We can expect the treatment of this disease to see further important changes in the next decades.

The IBTA gratefully acknowledges Dr Vijay Ramaswamy and Dr Eric Bouffet (both at SickKids Hospital in Toronto, Canada) for their advice about the contents and to Edwina Kelly (IBTA's graphic designer) for the illustrative representation of this timeline. ■

**2011-12:** Multiple genomic and next-generation sequencing studies reveal that medulloblastoma is a heterogeneous tumour comprising at least four distinct molecular variants (WNT, SHH, Group 3, Group 4). This provides an impetus for future research aiming at better outcomes with less toxicity to the developing brain.

**2012:** Results of the SIOP-PNET4 randomised study that assessed the role of hyperfractionated craniospinal radiation (HFRT). In this trial, HFRT was not superior to standard radiation, which therefore remains standard of care in medulloblastoma.

**1920s:** First attempt at x-ray therapy (roentgen therapy) by Percival Bailey and Harvey Cushing. They found that a subset of patients at autopsy in fact had no evidence of medulloblastoma, rather radiation necrosis. Led other groups to explore radiation therapy as a treatment after surgery.

**1950s:** First comprehensive study of craniospinal irradiation for medulloblastoma leading to three-year survival of over 50%. This showed for the first time that a combination of surgery and craniospinal irradiation could lead to cure and that medulloblastoma was not necessarily a fatal disease.

**1969:** Staging system proposed by C.H. Chang. This staging system was developed in the pre-CT scan era and is based on size and invasiveness of the tumour at surgery (T stage) and evidence of spread outside the posterior fossa (M stage).

**1970s:** First International Society of Paediatric Oncology (SIOP) and Children's Cancer Study Group (CCG) randomised trials with similar design (radiation +/- chemotherapy) that suggest a benefit for chemotherapy in a subset of patients.

**1920s:** Harvey Cushing described medulloblastoma and performed the initial surgeries. It was realized very quickly that after surgery, the tumour returns in all cases.

**1980s:** Several studies show significant neurocognitive impairment in children treated with standard doses of craniospinal irradiation, specifically young children. Approaches to reduce craniospinal irradiation using adjuvant chemotherapy are initiated. However, the SIOP 2 trial concluded that dose reduction was not safe.

**1990:** Introduction of the MRI scan of the spine in the staging of medulloblastoma (up to that time, spinal staging was performed with myelogram). This dramatically improved the ability to detect metastases and allowed more robust identification of high risk patients with metastatic dissemination.

**1993:** A Pediatric Oncology Group (POG) study evaluating chemotherapy only approaches for infants (Baby-POG) is published suggesting that a small proportion of infants could be cured without radiation therapy.

**2005:** A study from Germany reveals that a high proportion of infants with desmoplastic histology can be successfully treated with chemotherapy only.

**2013:** A study of recurrent medulloblastoma reveals that subgroup affiliation is stable at recurrence, and that Group 3 and 4 medulloblastoma frequently recur in the metastatic compartment. This suggests that progress in improving outcomes for these two subgroups must focus on treatment of the metastatic compartment.

**2014:** Several multicenter studies in North America and Europe are initiated evaluating de-escalation therapy for WNT medulloblastoma due to the excellent prognosis in this subgroup offering the possibility that this subset of patients can be cured with less neurocognitive and neuroendocrine sequelae.

**1997:** First evidence that deletion of the Patched1 gene is responsible for medulloblastoma formation in mice. This represents the first transgenic model of medulloblastoma.

**1999:** Results of CCG9892, a pilot study that shows an excellent five-year survival rate in children with average risk medulloblastoma treated with reduced dose radiation and chemotherapy combining cisplatin/CCNU/vincristine.

**2002:** First whole genomic analysis of embryonal tumours published by Pomeroy et al in Nature showing that medulloblastoma is distinct from other embryonal tumours of the central nervous system, in particular atypical/teratoid rhabdoid tumours and CNS-PNET. This study also showed that classic histology medulloblastoma has distinct profiles from desmoplastic histology.

**2005:** Nuclear beta-catenin identified as a marker of excellent prognosis in medulloblastoma, and is later shown to be a defining feature of the Wingless (WNT) subgroup of medulloblastoma.

**2006:** Genomic analysis of medulloblastoma reveals the existence of multiple molecular subgroups of medulloblastoma. This is the first study to suggest the existence of several distinct molecular variants of medulloblastoma.

**2006:** Multicentre studies initiated by the Children's Cancer Group (CCG9961) and St. Jude's (SJMB96) of reduced dose craniospinal irradiation followed by cisplatin-based adjuvant chemotherapy for average risk medulloblastoma patients showed five-year survivals of over 80%.

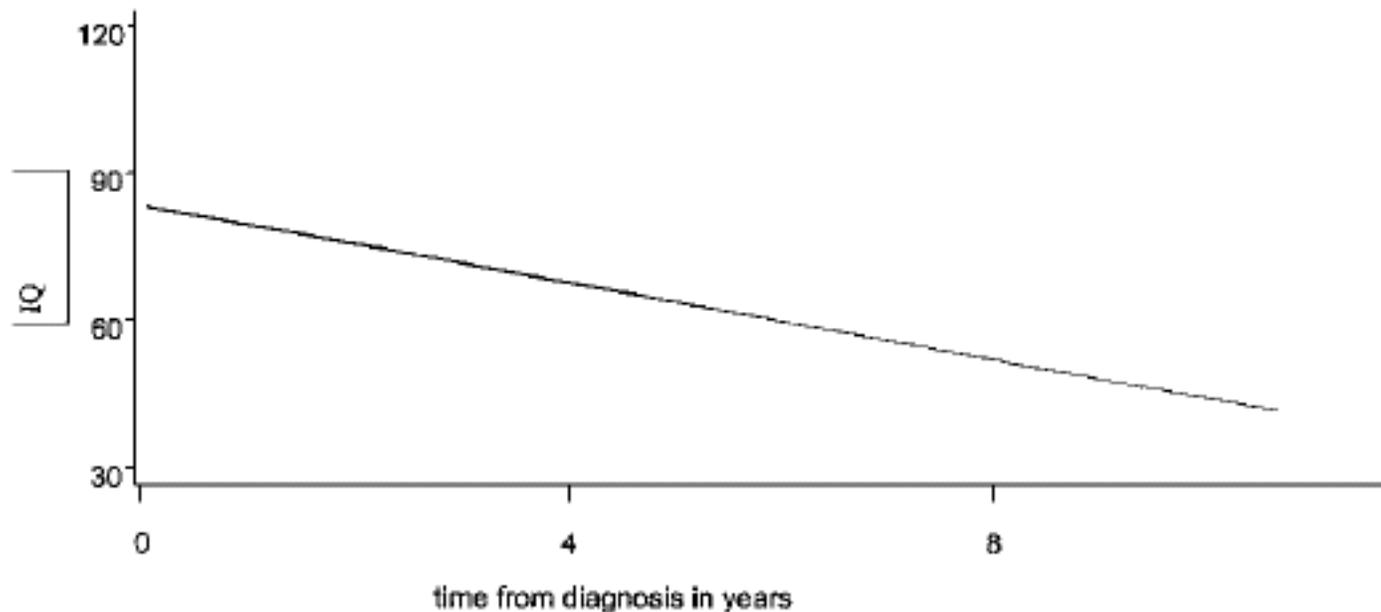

**2009:** Single case report of an adult treated with the smoothed inhibitor GDC-0449 reveals a dramatic but transient response, leading to several clinical trials of smoothed inhibition.

**2012:** A cross-species genomic study reveals that in disseminated medulloblastoma, the metastatic compartment is distinct from the primary tumour in both human and mouse medulloblastoma.

# “Infants” are especially vulnerable

Median age at radiation:

M0 patients: 2.9 years (1.3-5.3)

M+ patients: 3.3 years (2.1-5.1)

## *Neurodevelopmental Outcome*

Neurodevelopmental assessments are reported only for children who survived  $\geq 24$  months from diagnosis ( $n = 19$ ) so that meaningful conclusions can be drawn about survivors. All 19 subjects had  $\geq 2$  evaluations; a total of 65 test observations formed the basis for the neurodevelopmental analysis. Children lost significant cognitive function, as measured by IQ scores, during and after therapy ( $P = .0028$ ). The median baseline IQ value was 88 (range, 50 to 111), compared with 62 (range, 44 to 86) at our most recent follow-up evaluation, a median of 4.8 years (range, 2 to 10.6 years) after diagnosis. The rate of decline during this interval (Fig 4) was 3.9 IQ points per year (95% confidence interval, 1.12 to 5.60;  $P = .0028$ ). Cognitive losses do not yet seem to have reached a plateau. At the most recent evaluation, all children were receiving special educational services.

# Radiation avoidance in young children with MB associated with improved neurocognitive outcome

**Table 1. Chemotherapy Regimen.\***

Week 1	Week 3	Week 5	Week 7
Methotrexate (2 mg/day, intraventricular), day 1-4	Methotrexate (2 mg/day, intraventricular), day 1-2	Methotrexate (2 mg/day, intraventricular), day 1-2	Methotrexate (2 mg/day, intraventricular), day 1-4
Cyclophosphamide (800 mg/m <sup>2</sup> of body-surface area/day, intravenous), day 1-3	Methotrexate (5 g/m <sup>2</sup> , intravenous), 24 hr	Methotrexate (5 g/m <sup>2</sup> , intravenous), 24 hr	Carboplatin (200 mg/m <sup>2</sup> , intravenous), day 1-3
Vincristine (1.5 mg/m <sup>2</sup> , intravenous), day 1	Vincristine (1.5 mg/m <sup>2</sup> , intravenous), day 1	Vincristine (1.5 mg/m <sup>2</sup> , intravenous), day 1	Etoposide (150 mg/m <sup>2</sup> , intravenous), day 1-3

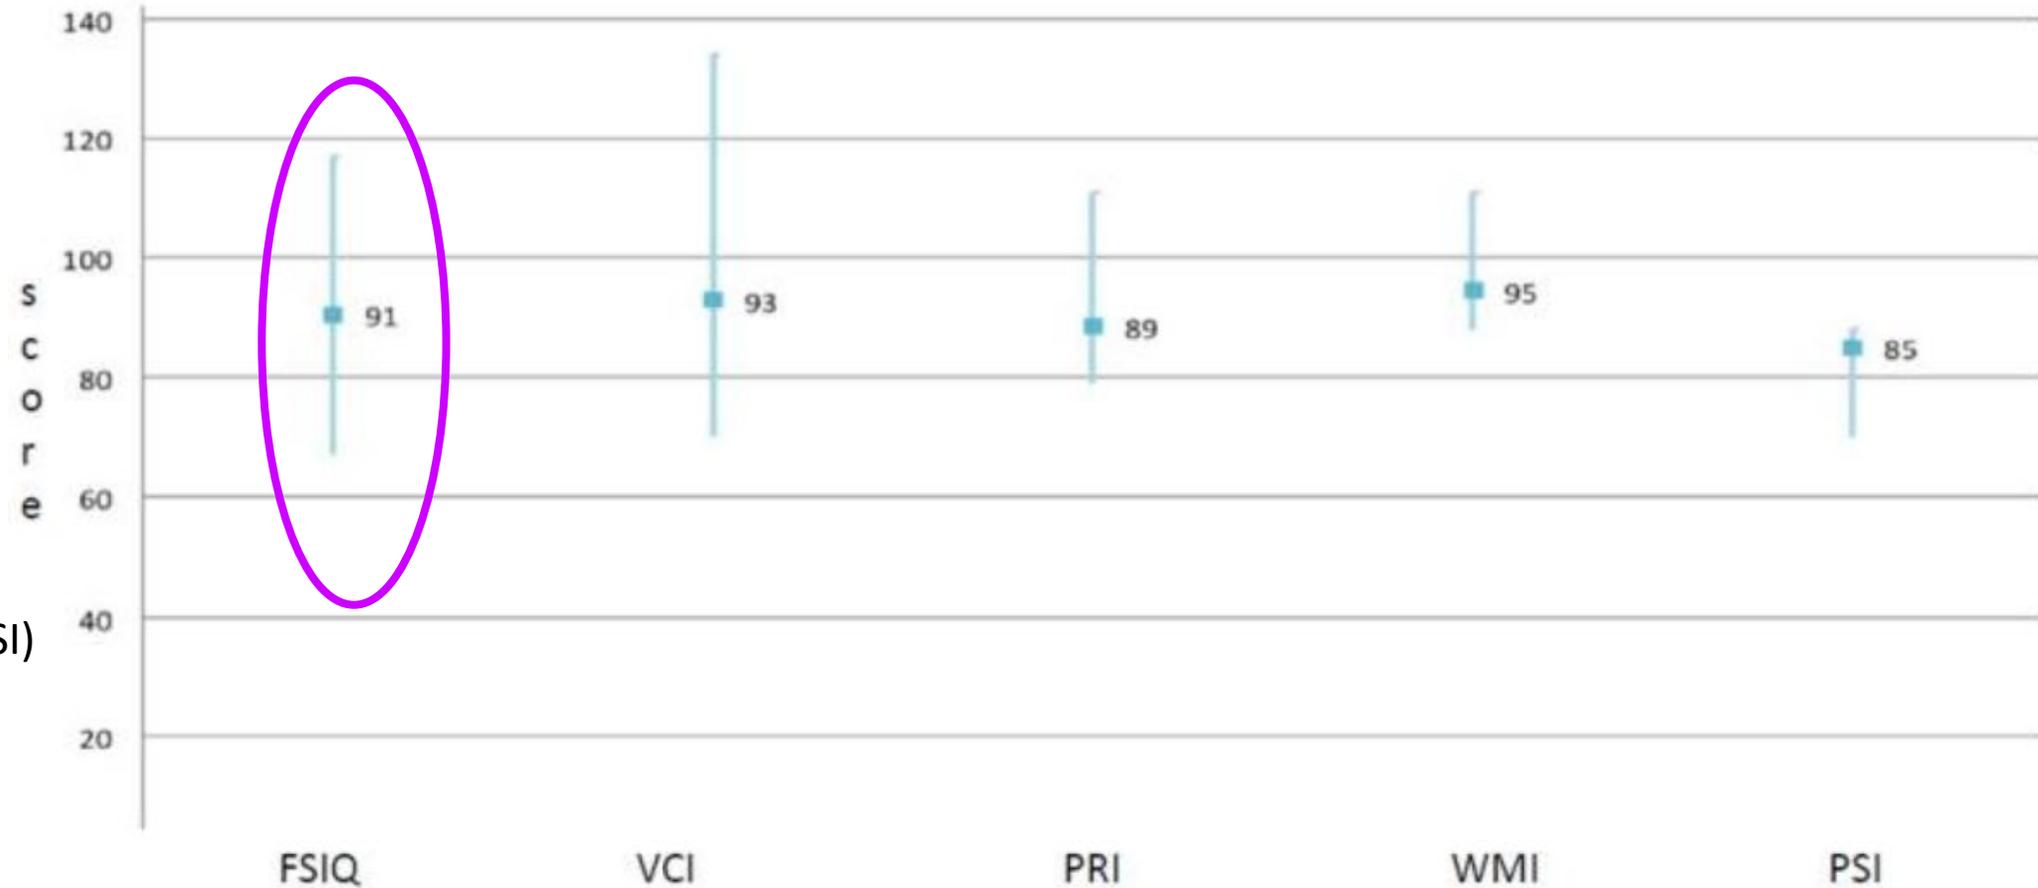

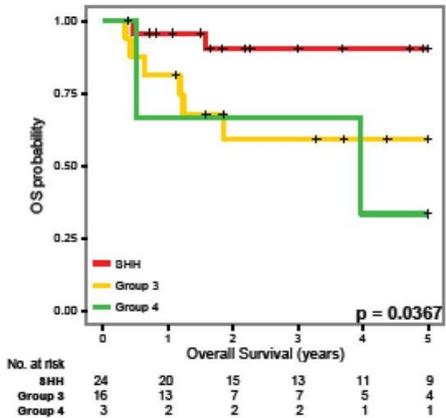

# Intraventricular methotrexate can be avoided for small subset of SHH MB

No. at risk:

MBEN	7	7	7	3	0
ND	18	7	5	1	0

# Radiation-sparing approach associated with cure for SHH and normal IQ scores

- 17 pts radiated
- 9 upfront (6 focal, 3 CSI)

# Infantile MB Summary

- Cure is possible with radiation-sparing approach, largely for SHH-MB
- Radiation avoidance associated with improved neurocognitive outcomes
- Definition of “infants” shifted over time - <5 y/o in Toronto

*What about older kids?*

Average Risk – 23.4 Gy CSI

High Risk – 36 Gy CSI

**Can we reduce this further??**

# 18 Gy CSI maintains outcomes for AR WNT MB

→ Ongoing trials with 18 Gy (COG) and 15 Gy (SJ)

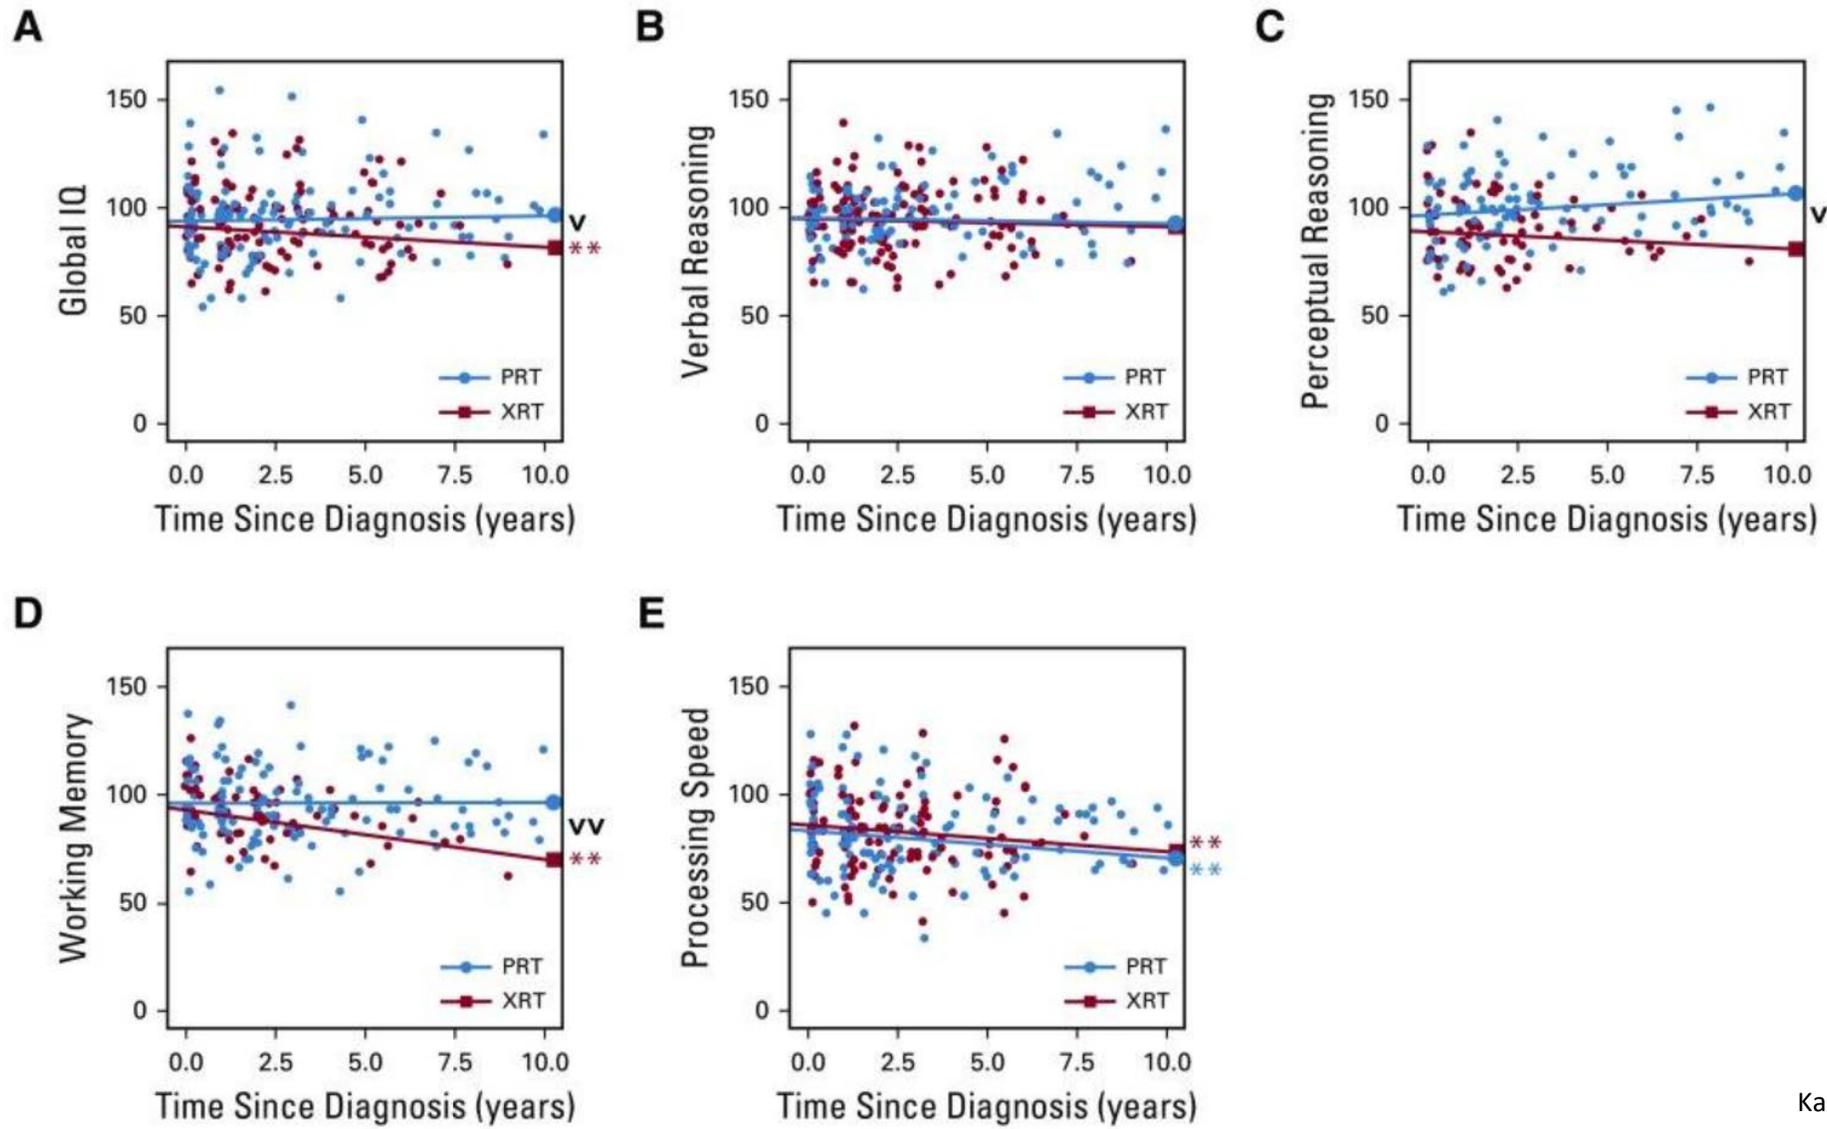

No. at risk:

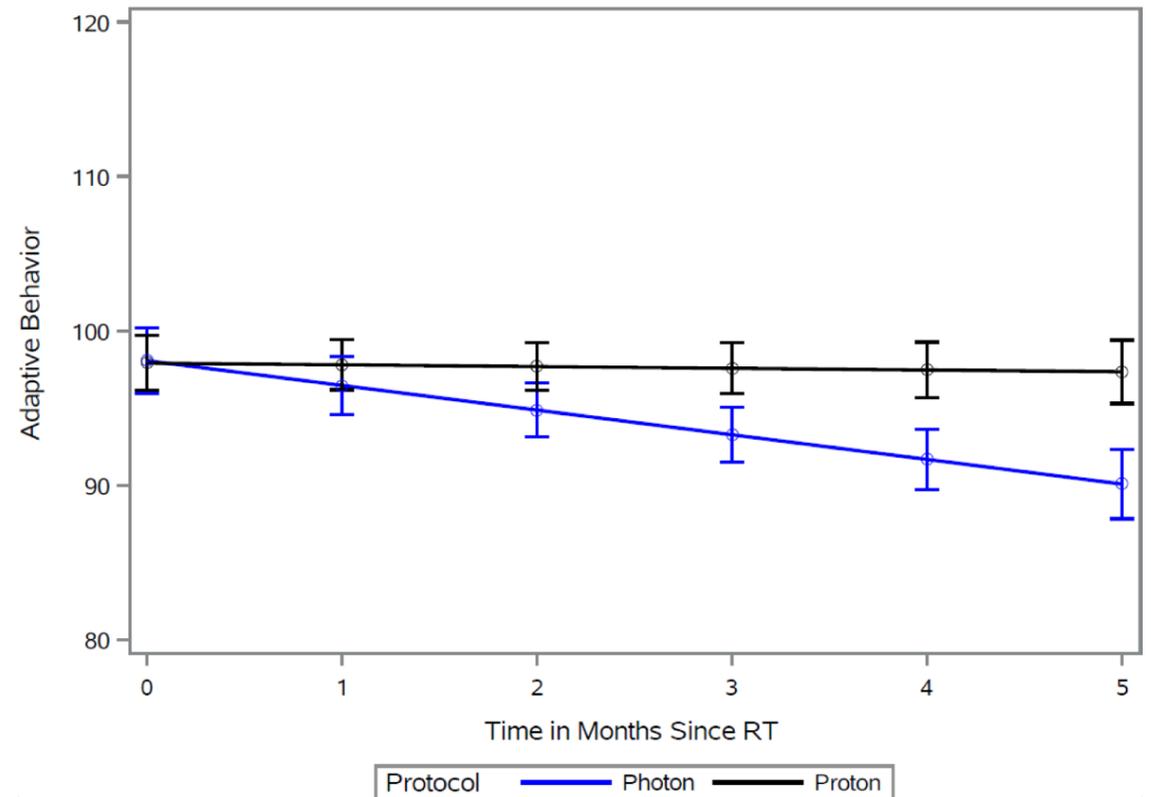

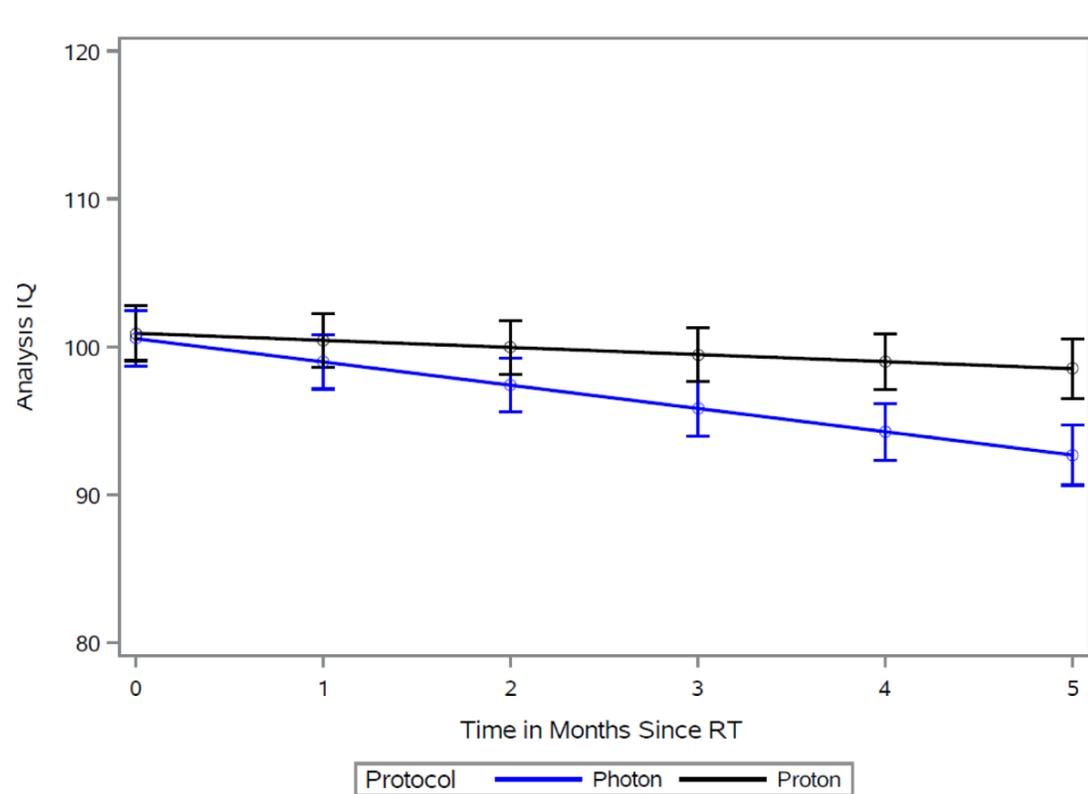

LDCSI	7	7	7	7	6	5	3	3	1	1	1	0	0	0
SDCSI	12	11	10	10	10	10	9	9	8	7	7	1	0	0

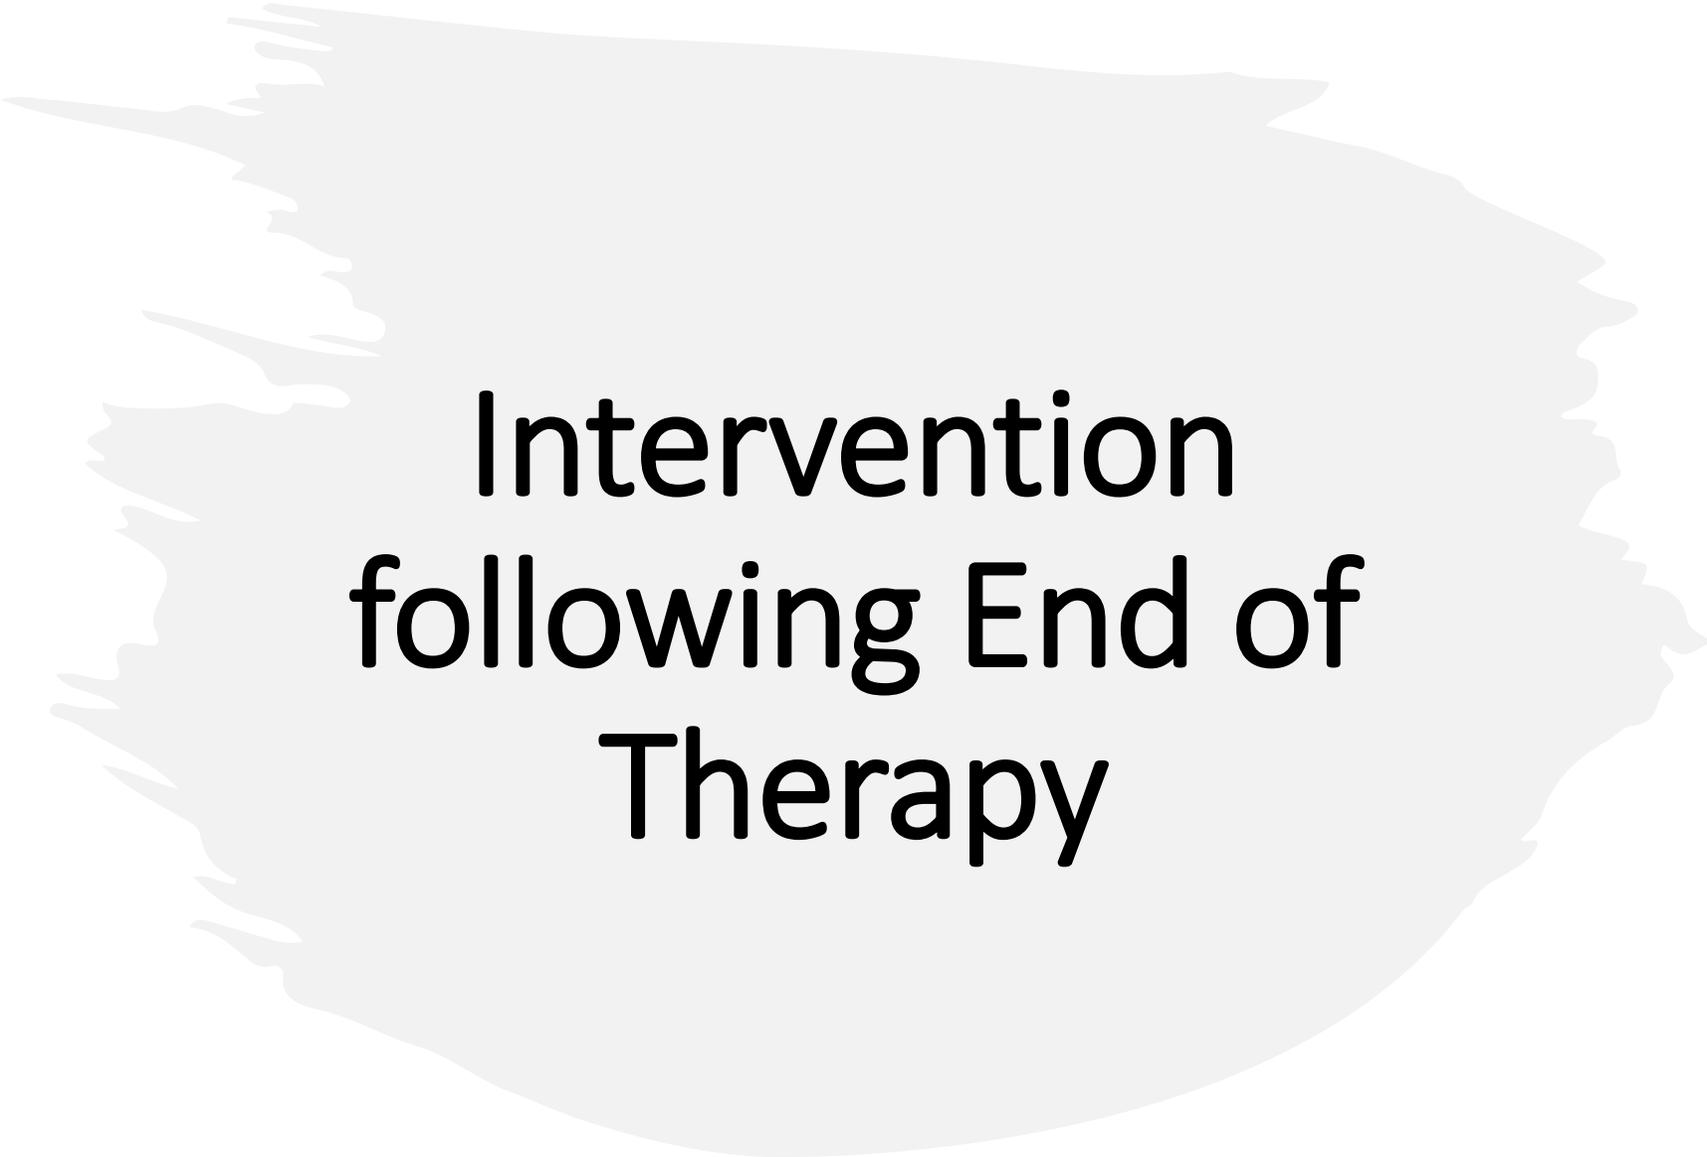

Does the type of radiation  
matter?

# Improved neurocognitive outcomes in MB treated with protons

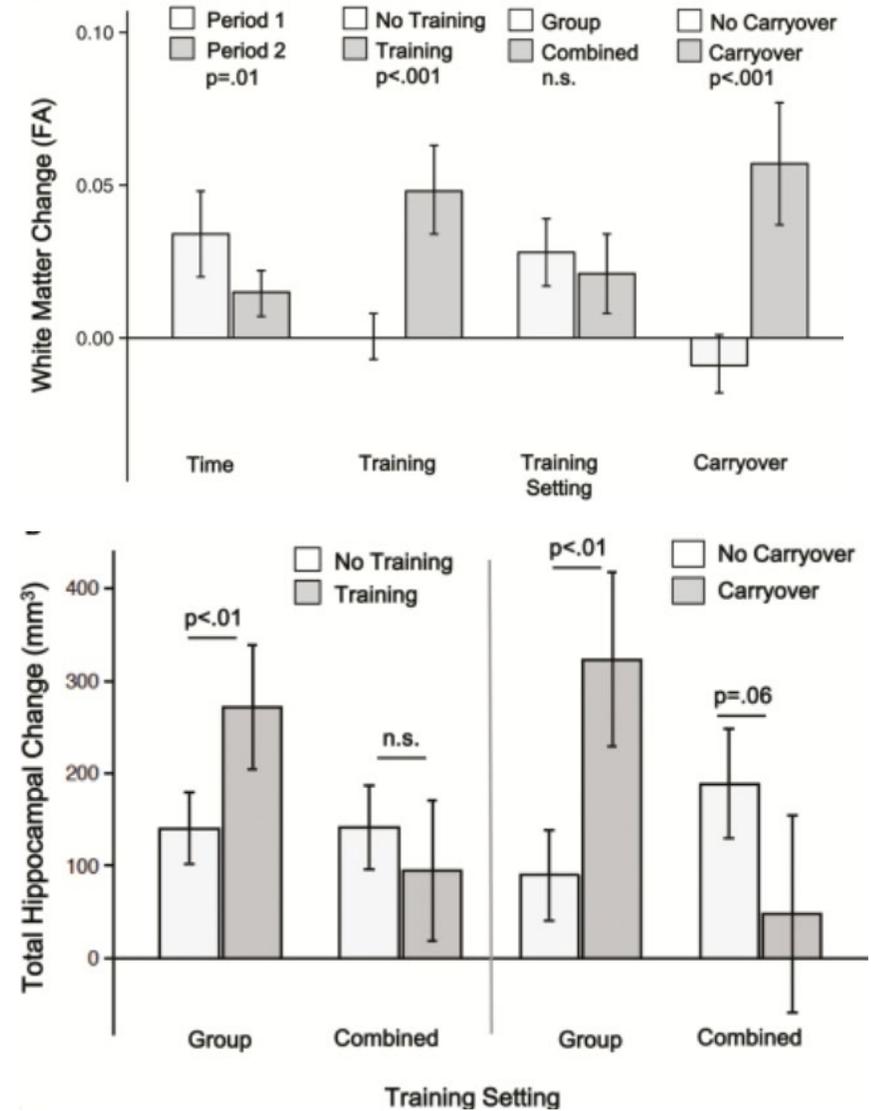

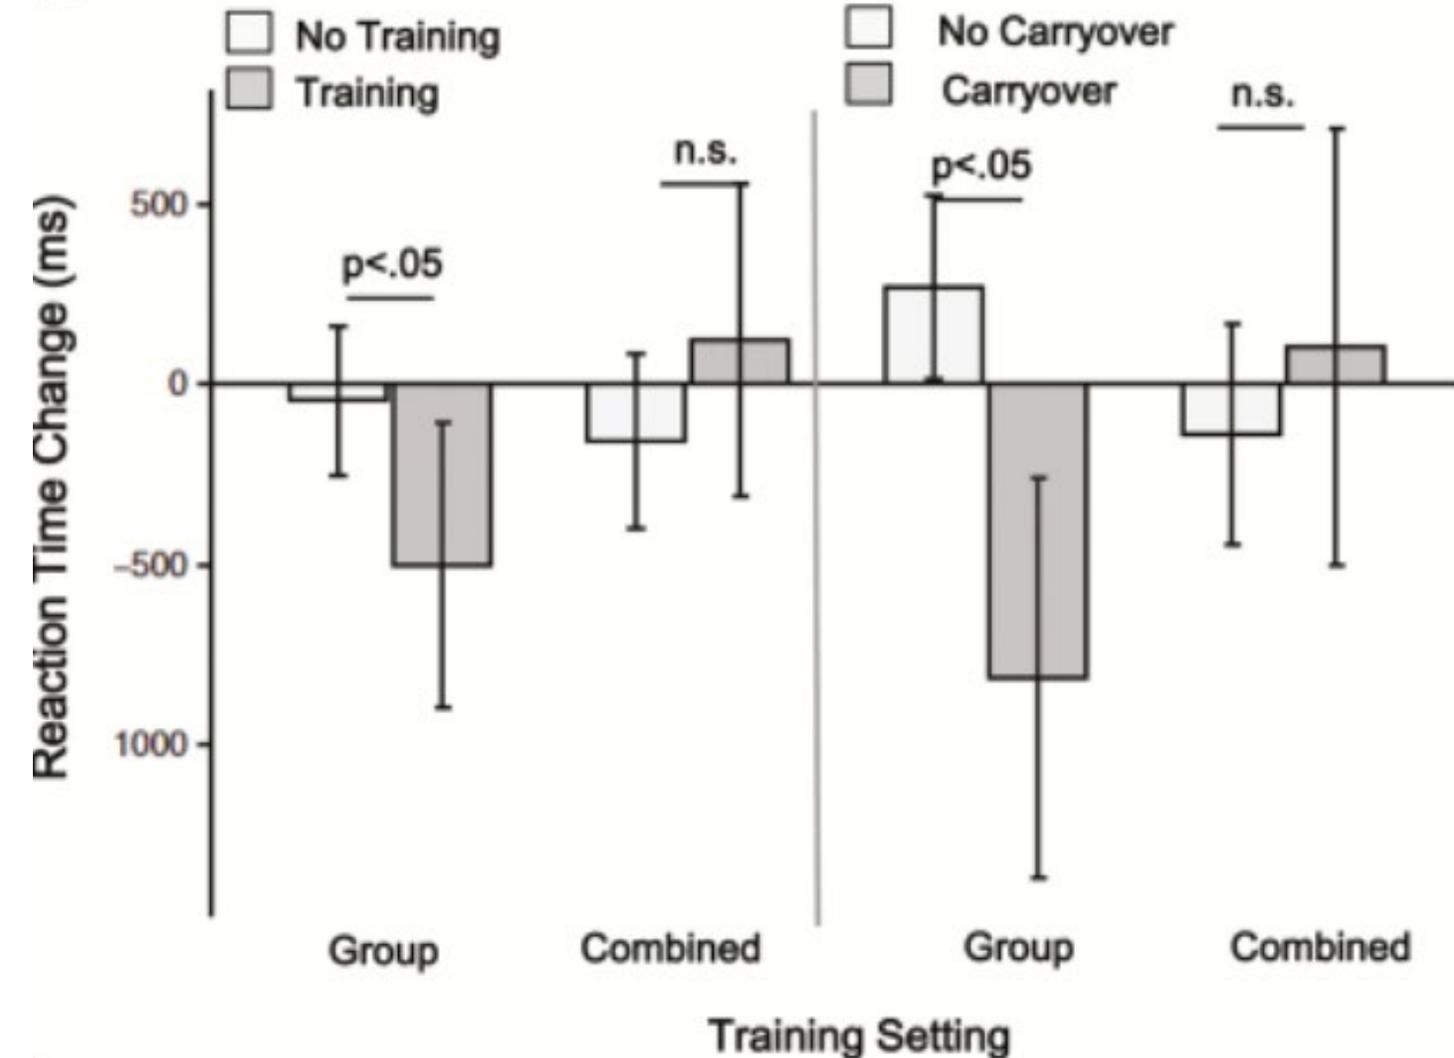

# Benefit of protons on neurocognition replicated in craniopharyngioma (focal RT)

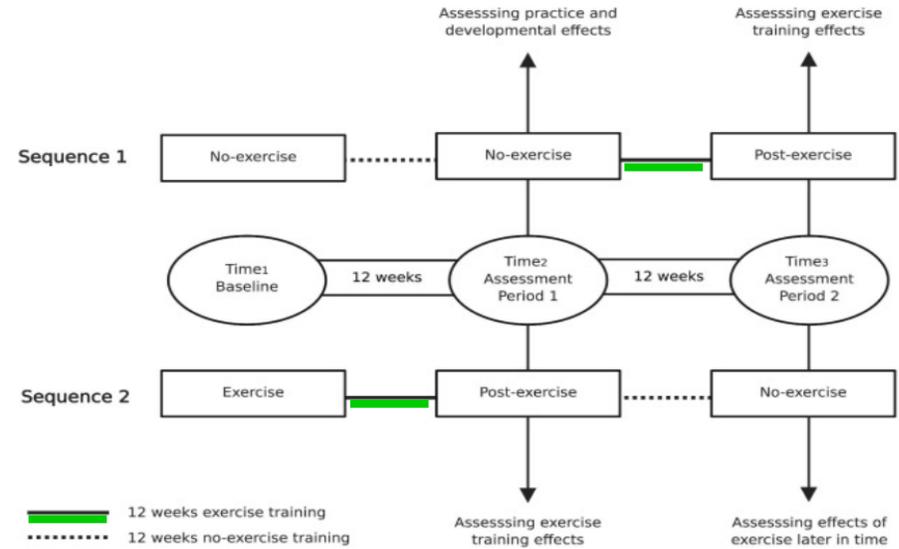

**Intervention  
following End of  
Therapy**

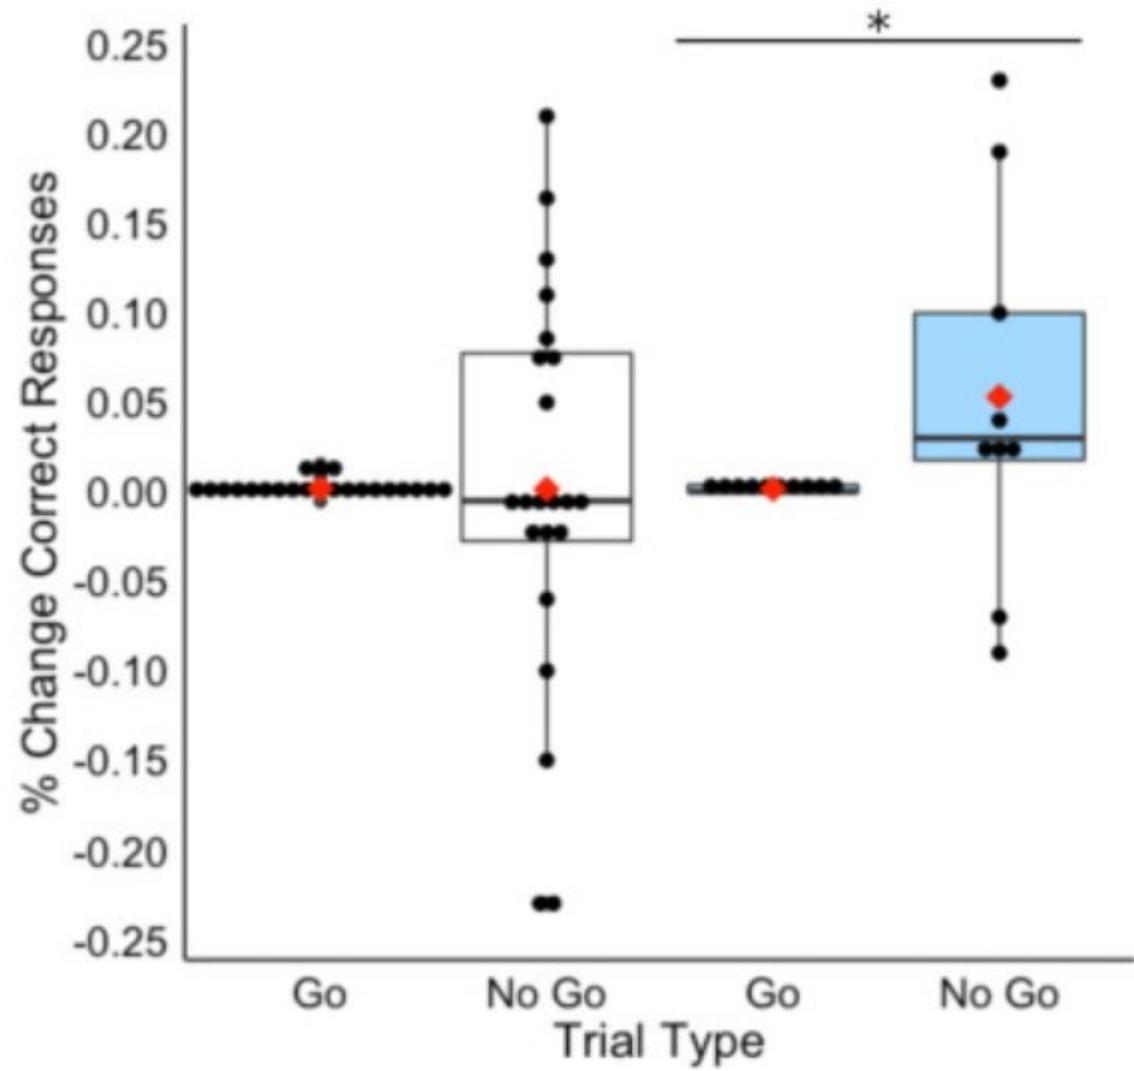

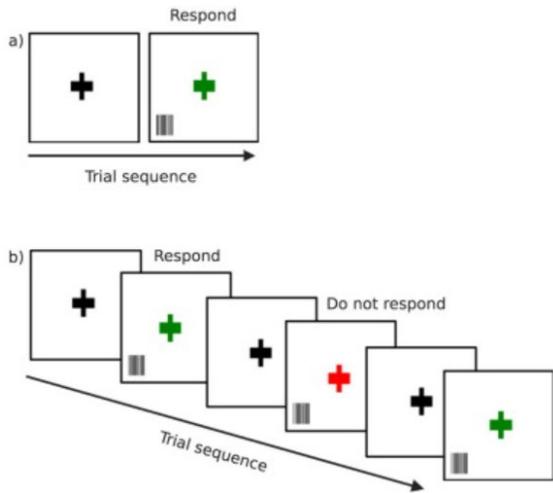

# 12 week exercise program improved reaction time in MB survivors

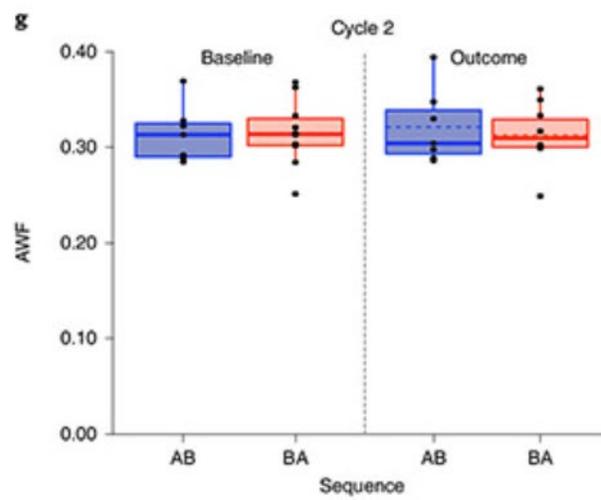

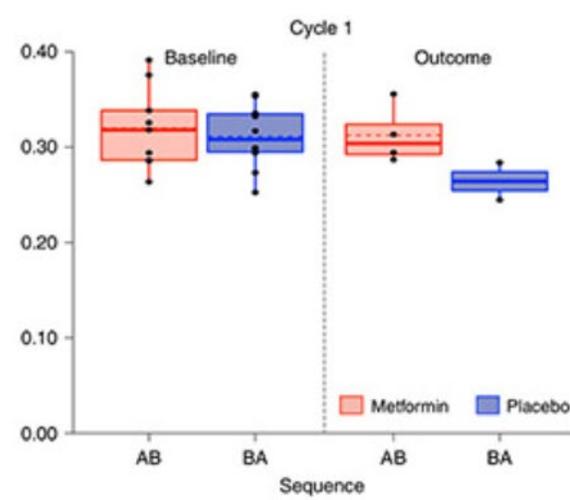

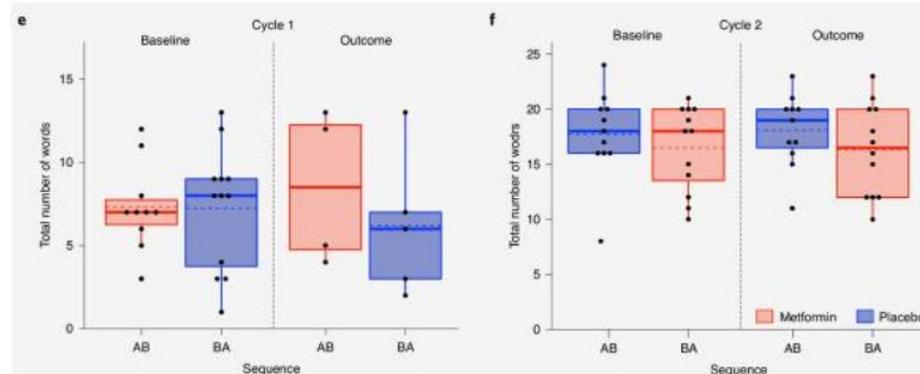

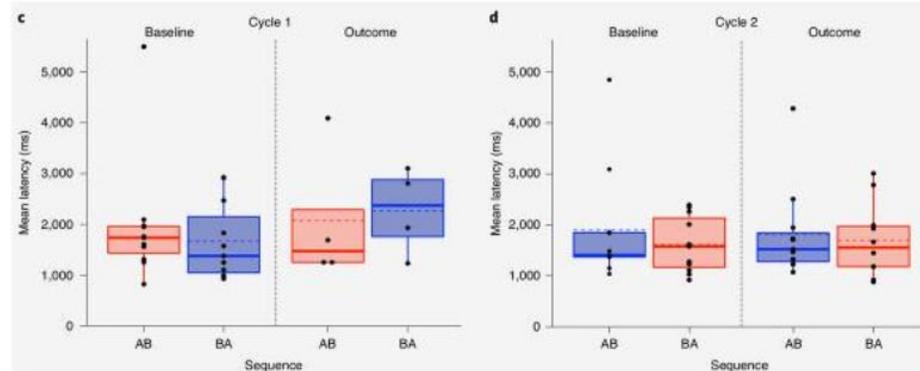

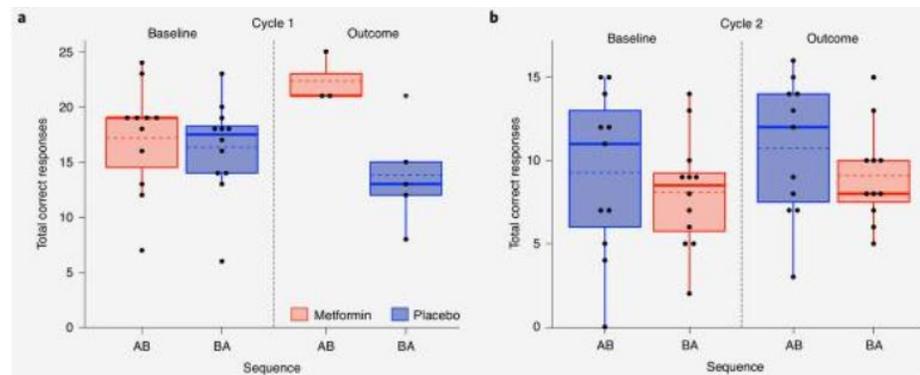

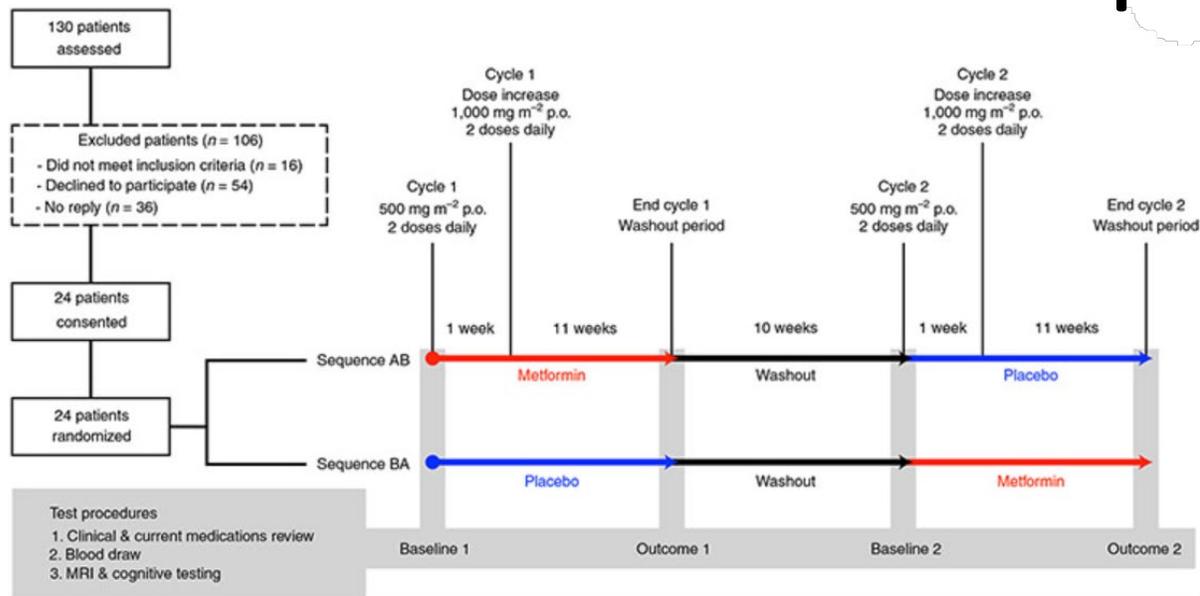

# Exercise may promote cognitive recovery in brain tumor survivors

MEG

# Metformin safe and encouraging results in pilot trial → phase 3 trial

# Conclusions

- Neurocognitive deficits are a major issue in the care of CNS tumor survivors
- Better understanding of tumor biology and use of newer treatment modalities can deliver tailored therapy resulting in reduced risk to neurocognition
- Novel therapies introduced after end of cancer treatment are currently being studied to improve neurocognitive outcomes
